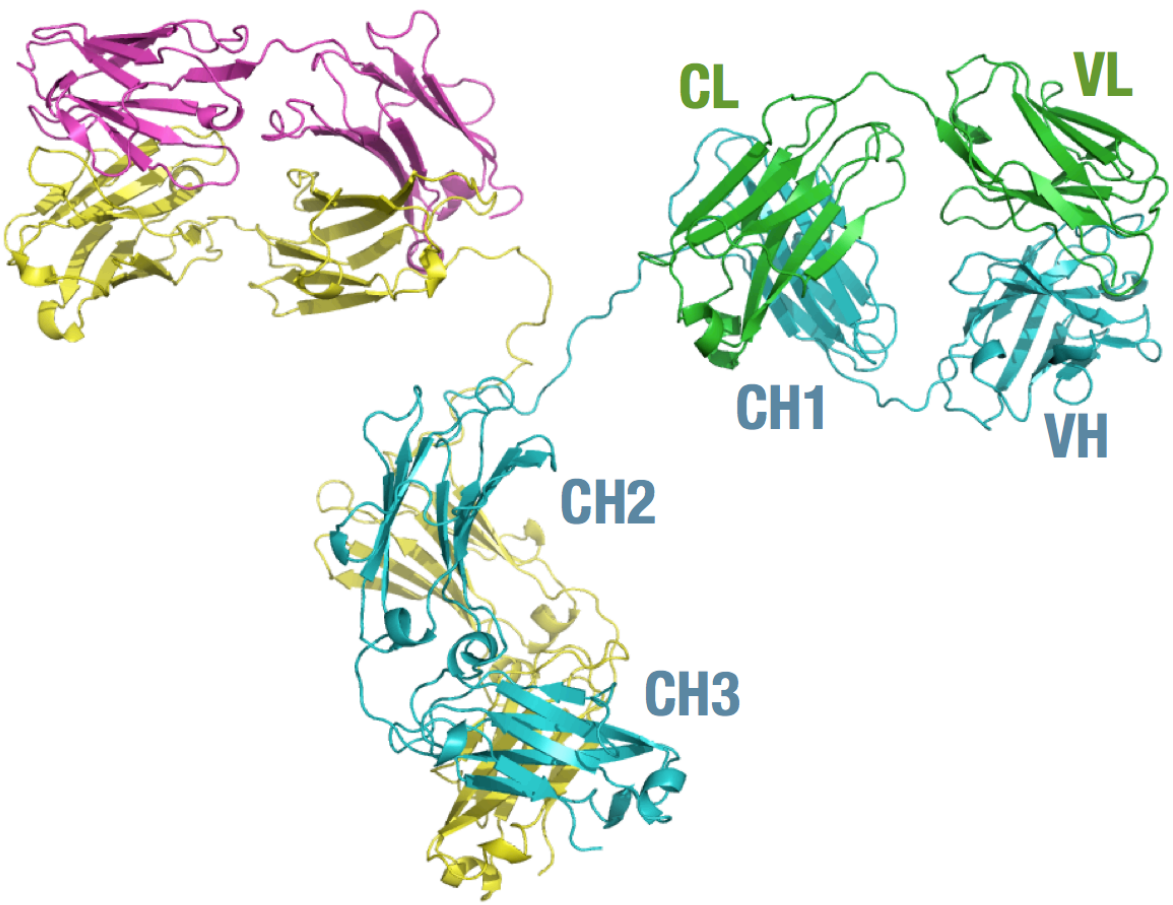
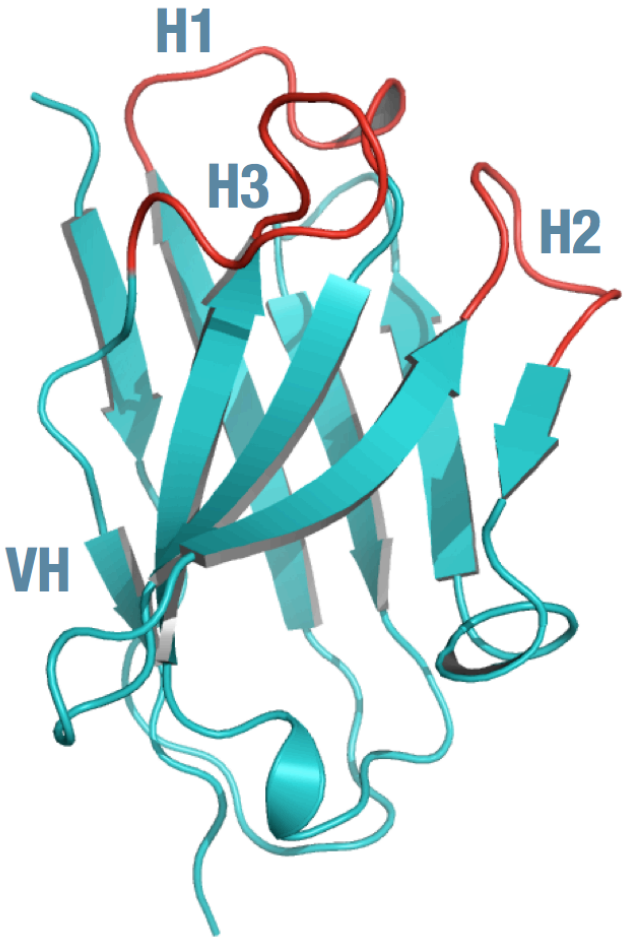
Basic properties

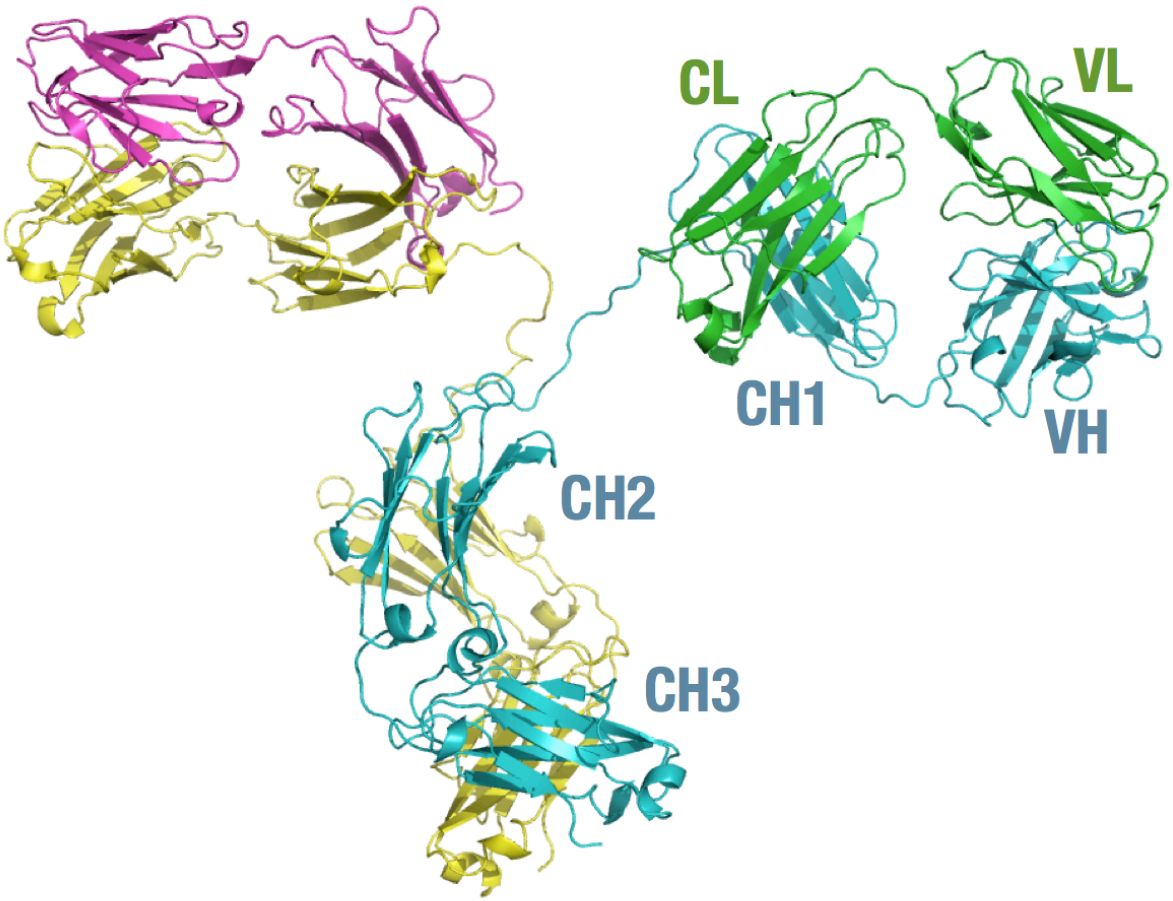


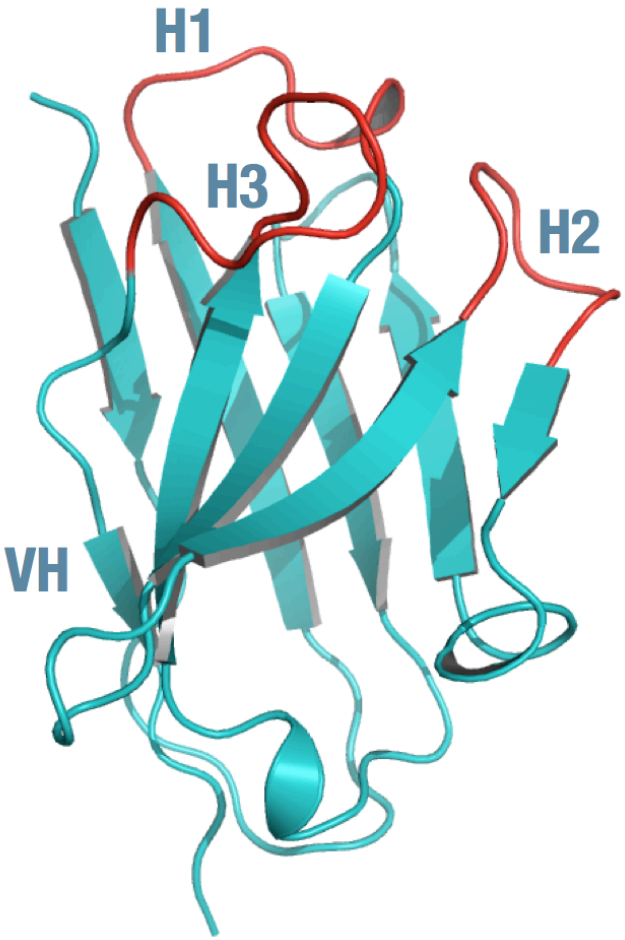


Basic properties

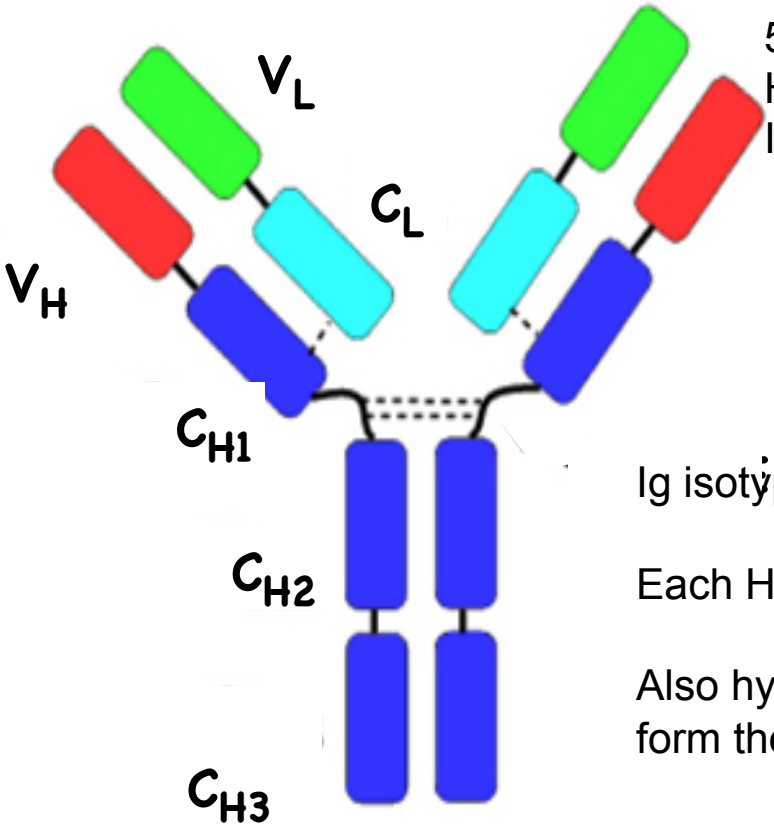
- Beta sandwich
- 2 light/alpha, 2 heavy/beta
- held together by disulphide

- 1 variable domain, 1 to 5 constant domains
- variable = antigen specificity
- constant = effector function





Ab STRUCTURE, cont.



5 types of heavy chain: μ, δ, γ (4 subtypes), ε, α.
H chain defines <u>class</u> (isotype) of Ig: IgM, IgD, IgG, IgE, IgA

Ig isotypes play different roles in immune responses.

Each H or L chain composed of a C and a V region.

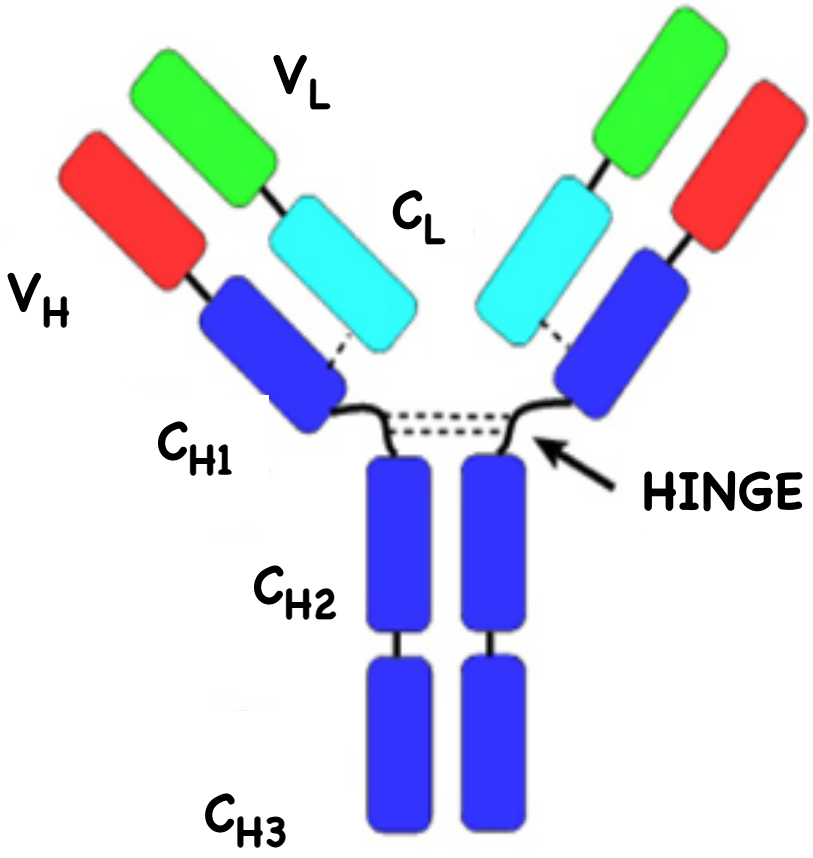
Also hypervariable regions interspersed throughout V. These form the 3-D structure of the Ag binding site.

CLASSES AND SUBTYPES OF HUMAN Ig

property	Ig class or subtype							
	IgM	IgG1	IgG2	IgG3	IgG4	IgA1,2	IgE	IgD
form	pentamer	mono	mono	mono	mono	dimer	mono	mono
serum level (mg/ml)	1.5	9	3	1	0.5	3.5	0.00005 #	0.03
Complement activation	+++	+++	+	+++	-	-	-	-
Placental transfer	-	+	+	+	+	-	-	-
macrophage (Fc receptor) binding	-	+	-	+	-	-	-	-
present in external secretions	mucus* etc	milk *	milk *	milk *	milk *	mucus* etc	-	-
mast cell/ basophil degranulation	-	+*	-	-	-	-	+++*	-

*(species-dependent) # value is for non-allergic individuals

Ab STRUCTURE, cont.



H have 4 domains
Amino terminal variable domains (V_H) at the tips of the Y

3 constant domains: CH1, CH2, and the COOH terminal CH3, at the base of the stem

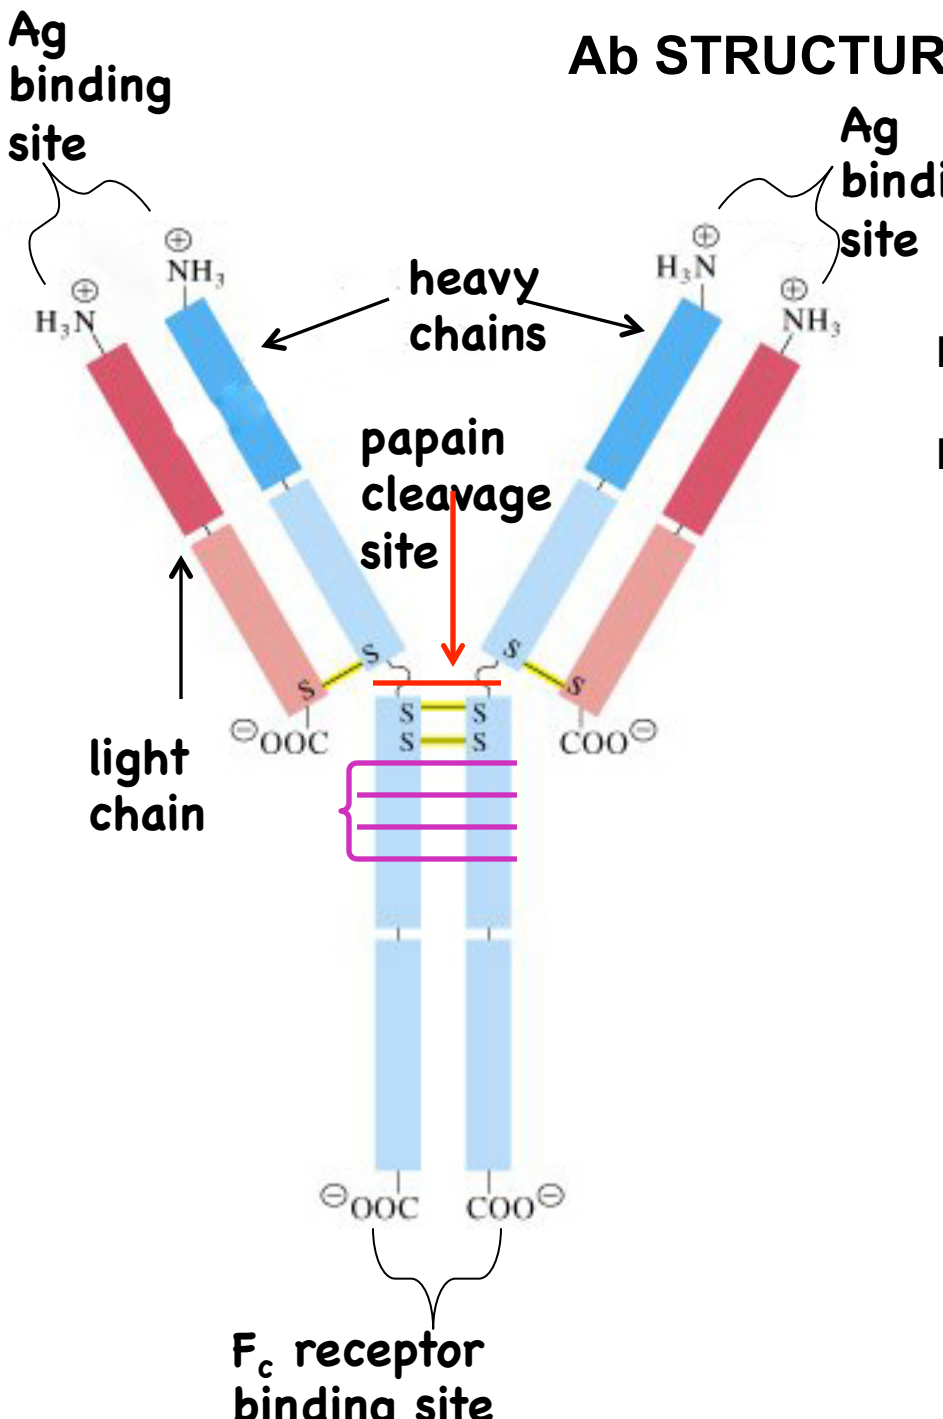
Switch connects the constant and variable regions

Hinge connects CH2 and CH3 (the F_c fragment) to the rest of Ig F_{ab} fragments).

L chains - 2 domains, variable (V_L) & (C_L), connected by a switch.

Individual B cells synthesize Abs of a single specificity (same H, same L).

Ab STRUCTURE, cont.

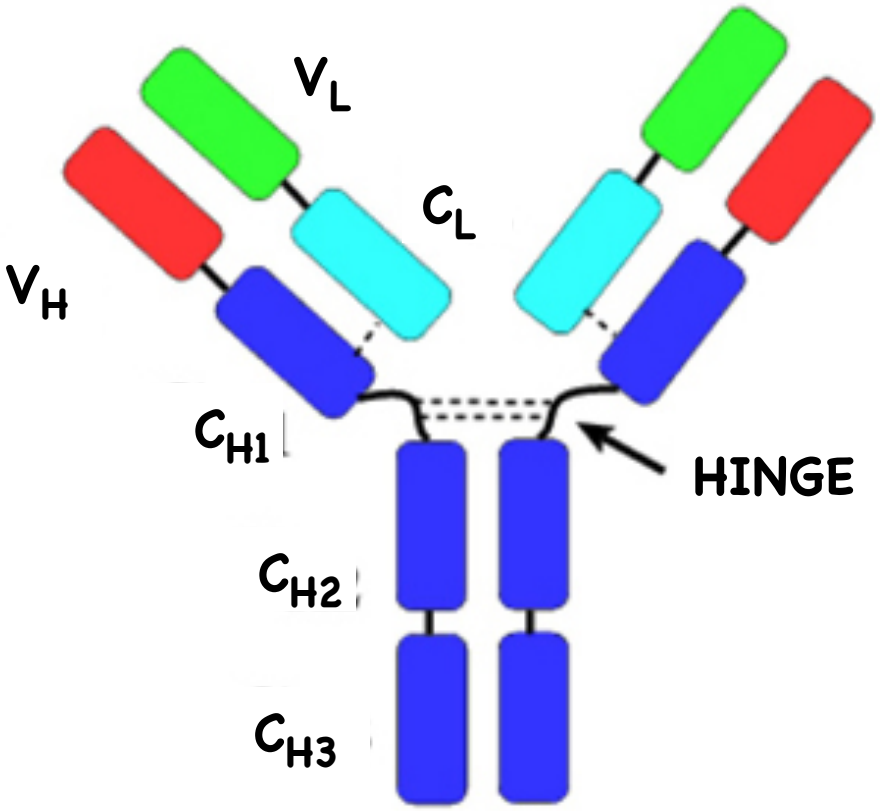


Cleavage of Ig with papain yields 3 fragments of 2 types:

Fab: has antigen (Ag) binding site.

Fc: C = crystal; this portion of Ig 1st to be crystallized. F_c binds to cell surface F_c receptors, augmenting immune responses (opsonization, e.g.).

Ab STRUCTURE, cont.



V of both L and H Ig chains contain 3 hypervariable regions, or complementarity-determining regions (CDRs).

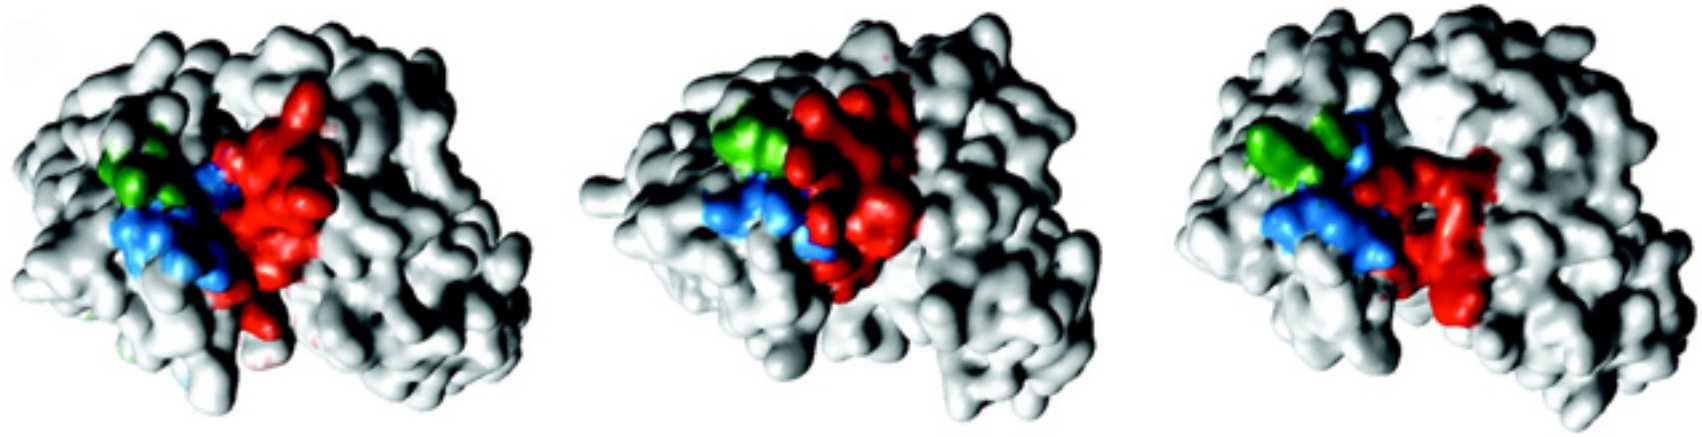
CDRs = loops connecting β strands in Ig fold

Residues in CDRs vary from one Ab to the next, **imparting Ag specificity to each Ab**.

V_L and V_H domains at tips of Abs packed so that 6 CDRs (3 on each) form surface for Ag-specific binding.

Residues from all 6 CDR's (V_L CDR1, CDR2, CDR3 & V_H CDR1, CDR2, CDR3) project from distal surface of Ab tip to bind Ag.

EFFECT OF SEQUENCE ON Ab BINDING SITE & Ag SPECIFICITY



from Lantto, J., et al. J. Biol. Chem. 2002; 277: 45108-45114.

red = CDHR3; blue = CDHR2; green = CDHR1

CDHR = complementarity-determining region of H chain (hypervariable region)

Effect of insertions/deletions on Ag binding

Canonical Structure prediction

Given an antibody sequence
we can predict the CS of each loop (H3 is kind of an exception)

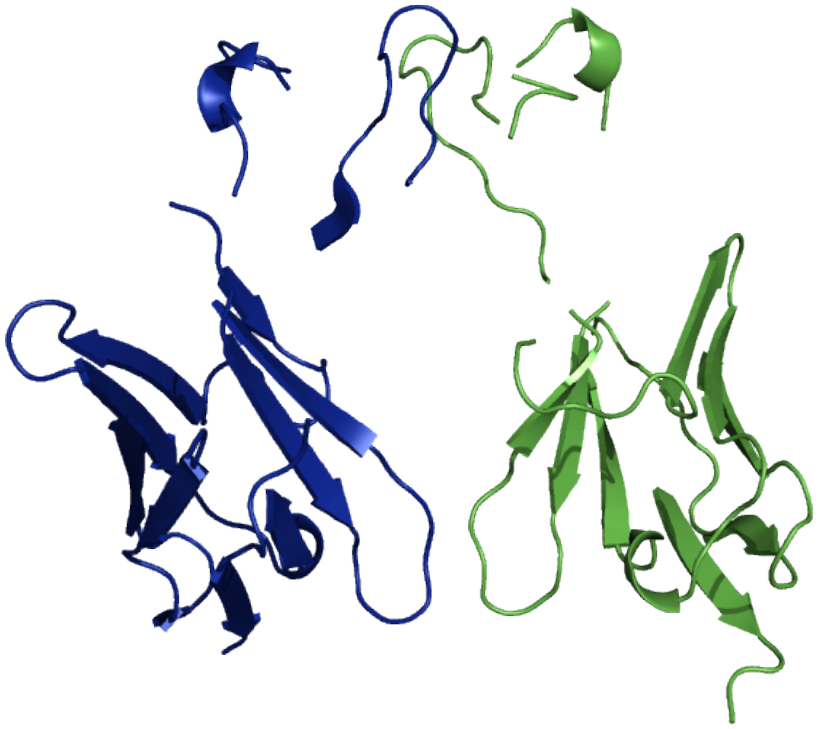
PIGS

Frameworks (L & H) selection based on %id

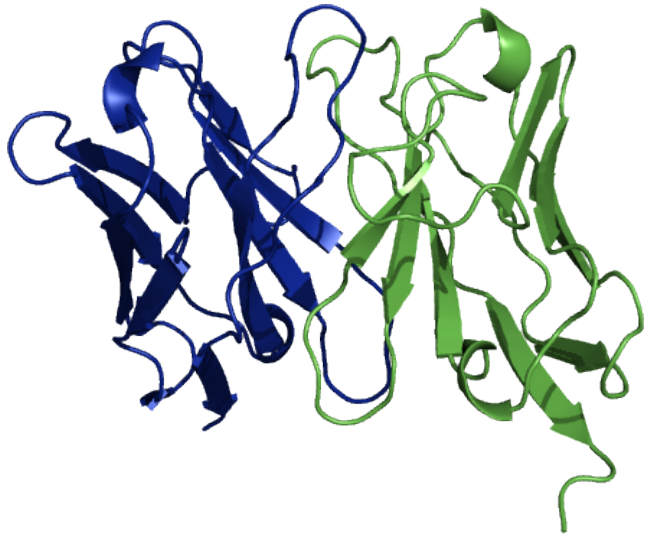
PIGS

Loop selection (L1-3, H1-3) based on CS + %id



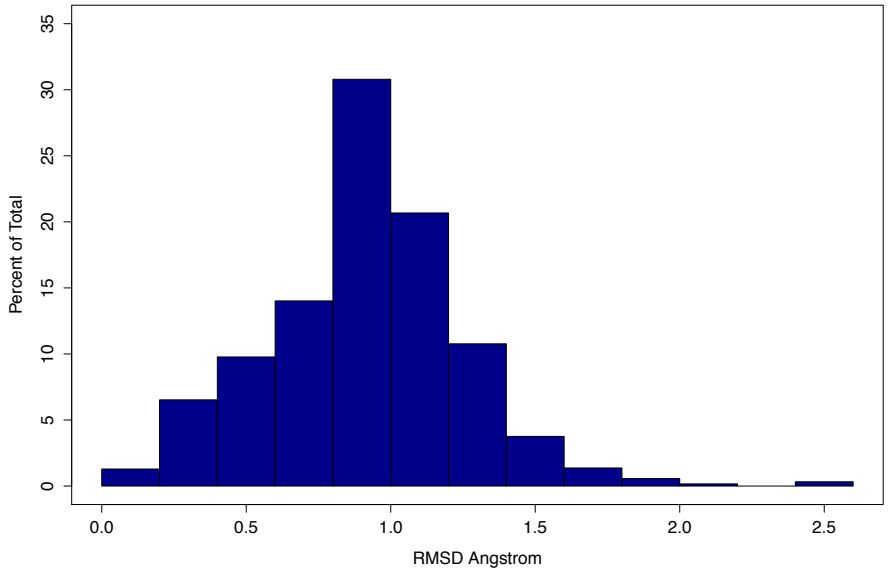
PIGS

VL-VH packing
Superpose loop stems
Side Chains (SCWRL)

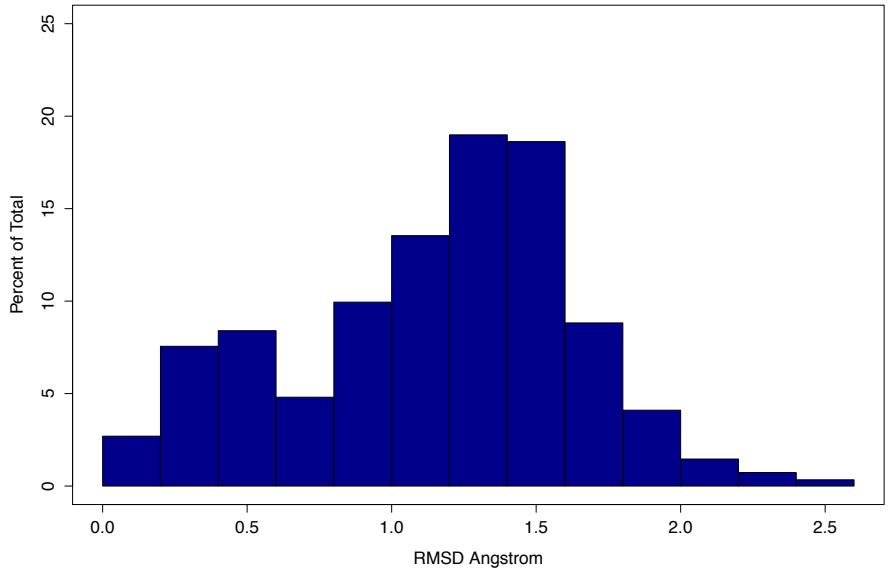


Assessment

Whole Fv



ABS (all CDRs)



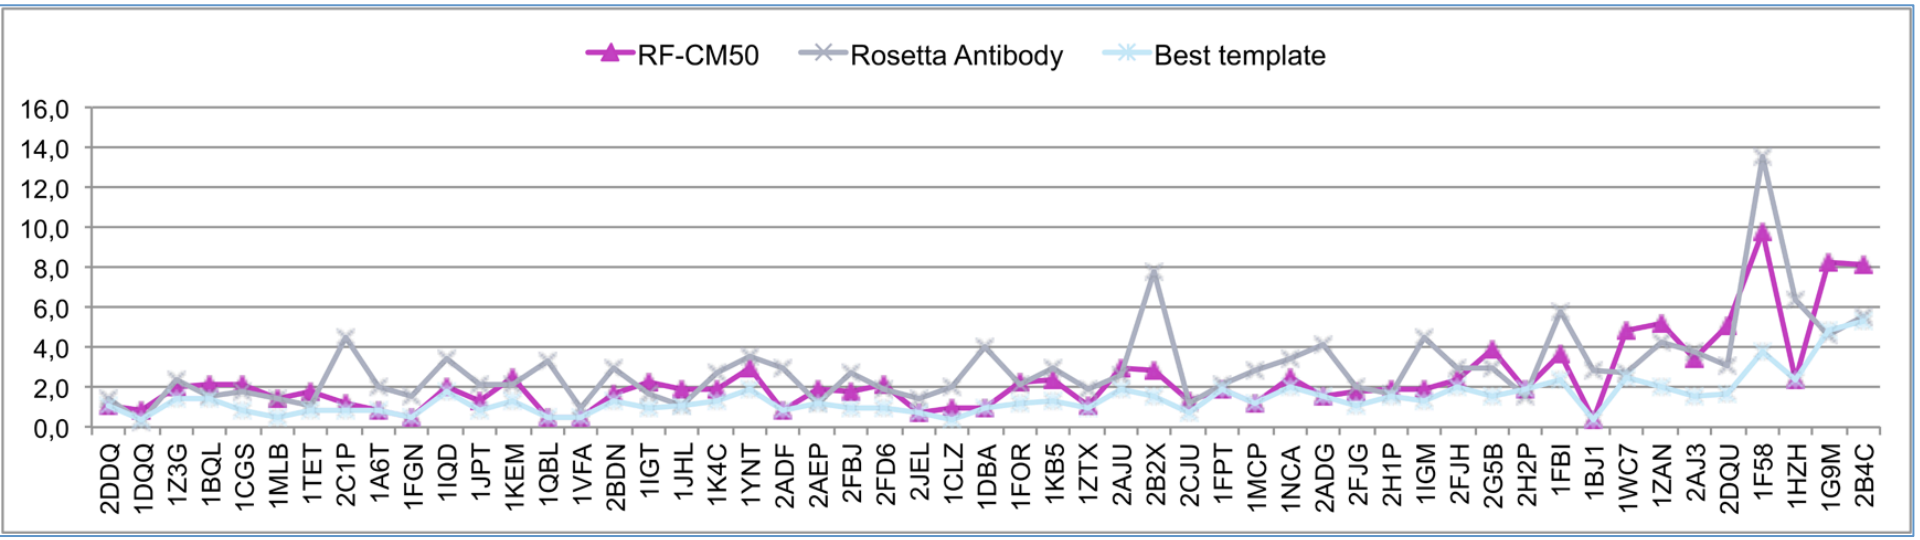
H3 Prediction

H3 HCDR3) is:
The longest loop (up to 25 residues)
(Almost) no CS
The most flexible
The most important for recognition
The hardest to predict

H3 accuracy

Good (~1Å) for short loops

Bad (up to 6Å and more) for long loops



TCR models

We have > 1500 solved antibodies

TCR: ~50

No method currently available!

Problems in modeling

H3 models are unreliable

Bias on Human and Mouse antibodies

Role of glycosilation

Signal transduction

Take home

The antibody fold is one of the most common
beta-sandwich

CDRs are located on loop regions
extremely variable in sequence, not in structure (backbone!!!)

Canonical structure method

Models are extremely reliable (with the exception of H3)
